

Biomass Carbon Removal and Storage (BiCRS) and Direct Air Capture (DAC): Impacts and Research Needs in California

EPIC Strategic Goals Emerging Strategies Workshop:

September 20, 2023

Sarah Baker

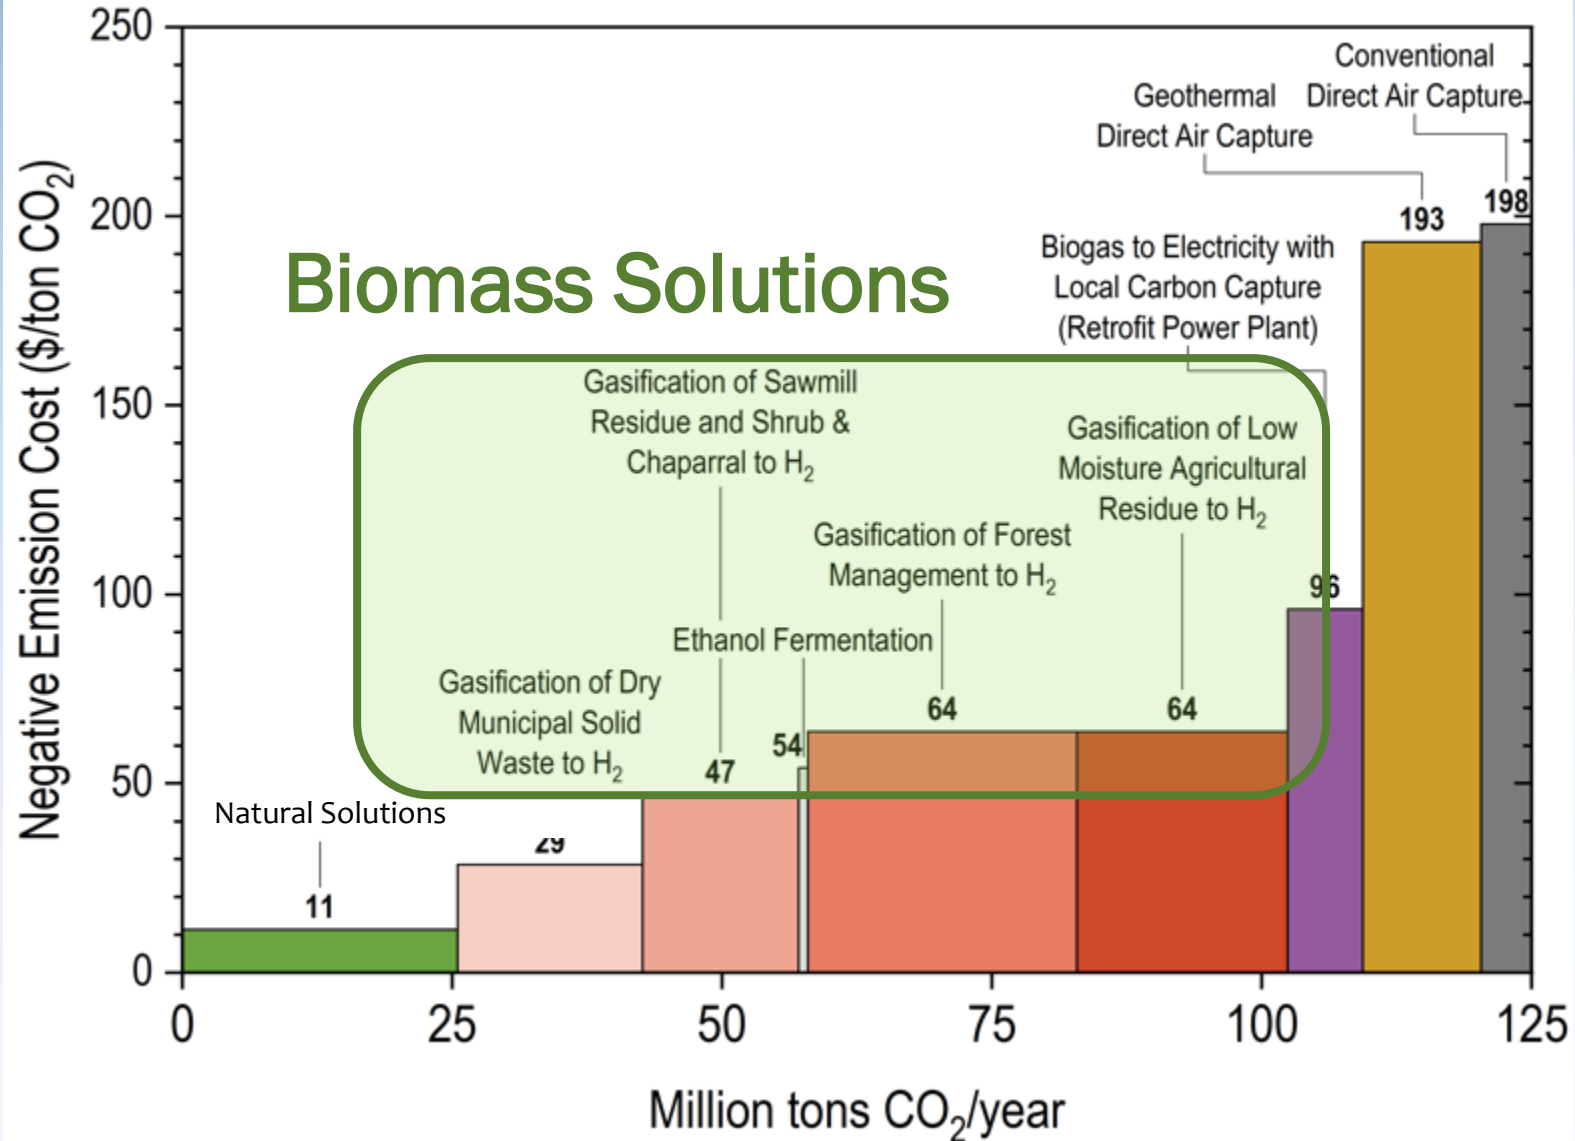

California's Path to Zero Requires Carbon Removal

LLNL estimated that 125 M tons/yr of negative emissions capacity would comfortably meet the need – especially if some measures are slow

California's least-cost path to 125 Mt/year of durable carbon removal averages ~\$60/ton

Getting to Neutral Results: The lowest cost set of solutions for removing 125 million tons of CO₂

- Natural and Working Lands

25 MT/year

- BiCRS: Conversion of Waste to Fuels with CO₂ Storage

84 MT/year

- DAC: Direct Air Capture with CO₂ Storage

16 MT/year

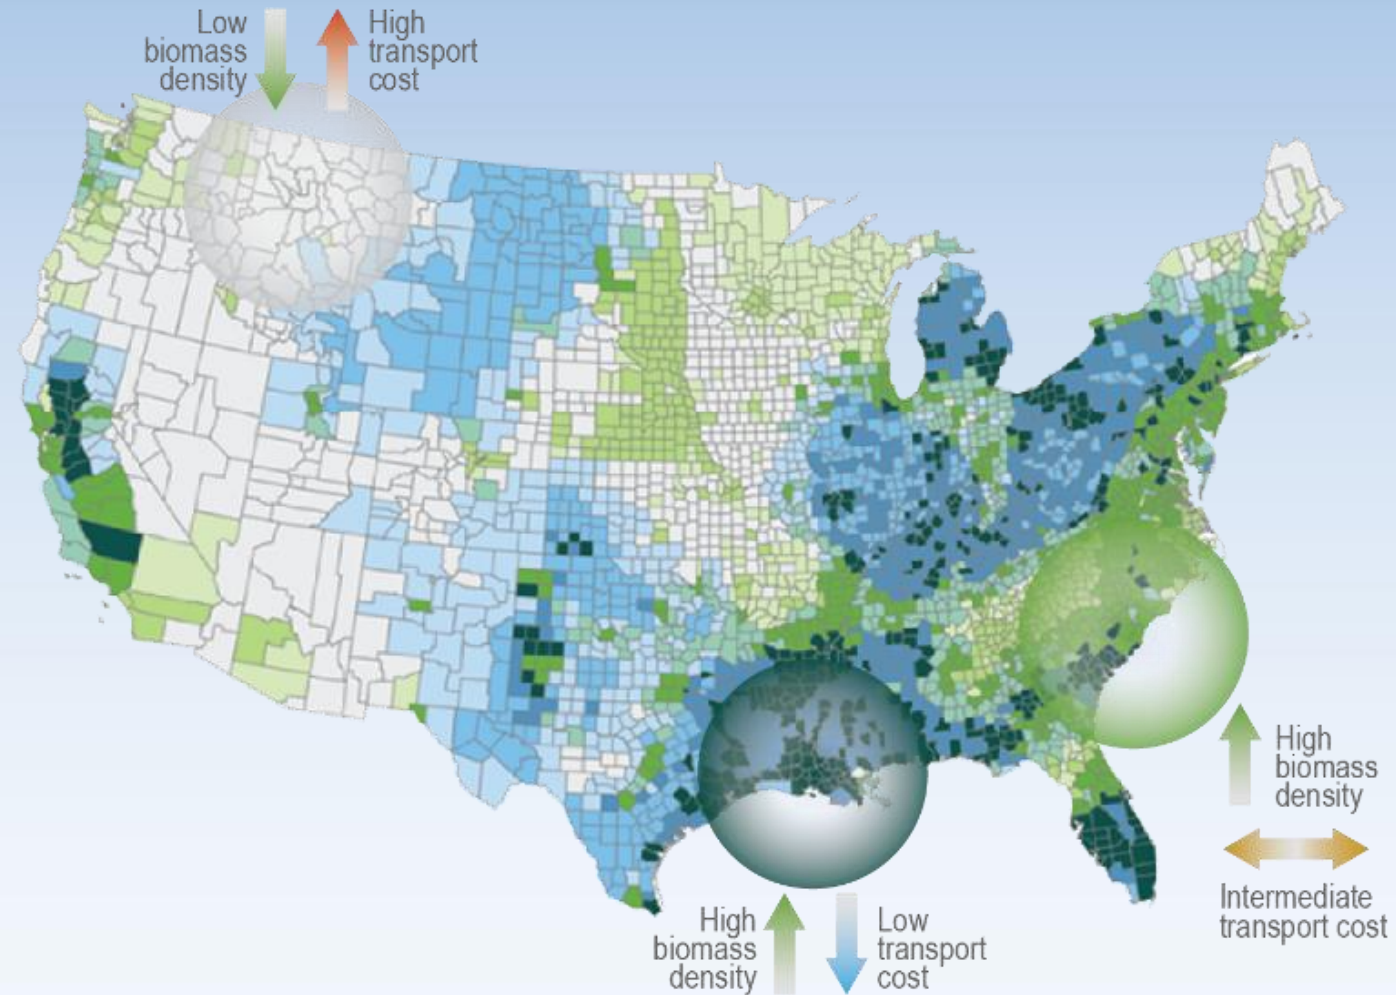

Technological readiness: mid-to-high—with substantial co-benefits for CA, but significant implementation barriers remain for BiCRS and DAC

Biomass Carbon Removal and Storage

Put waste biomass to work to reach climate goals

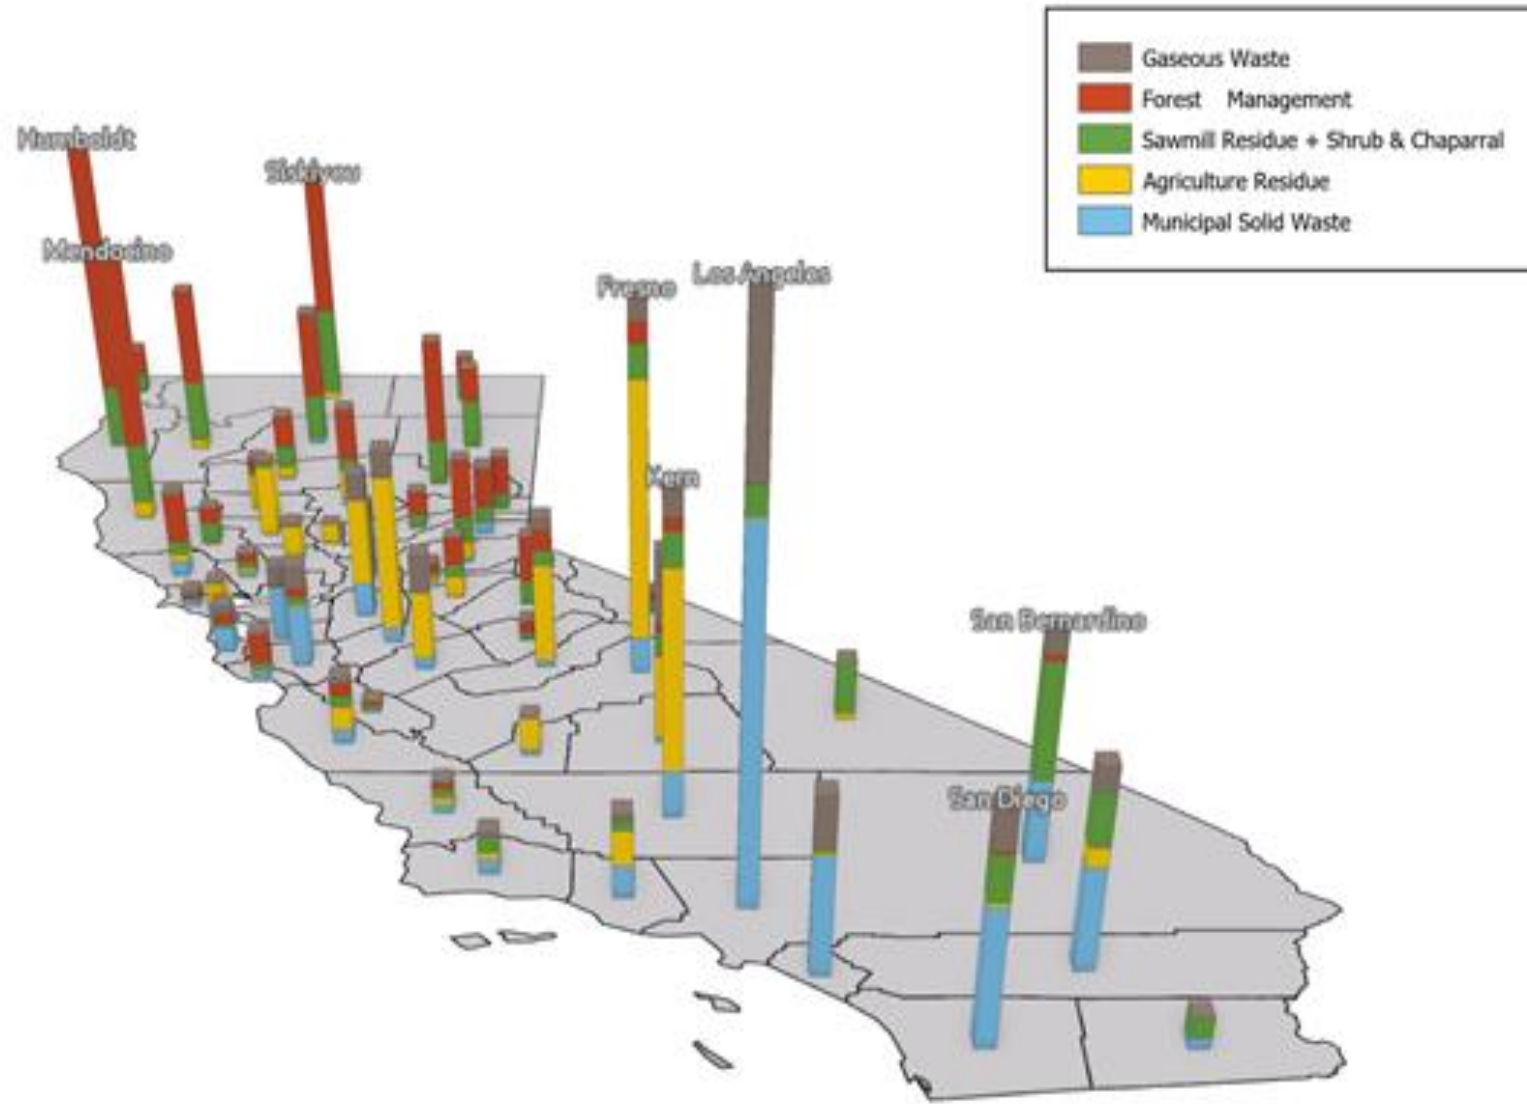

The regions of highest opportunity for BiCRS are located where there is abundant waste biomass and local geologic carbon storage

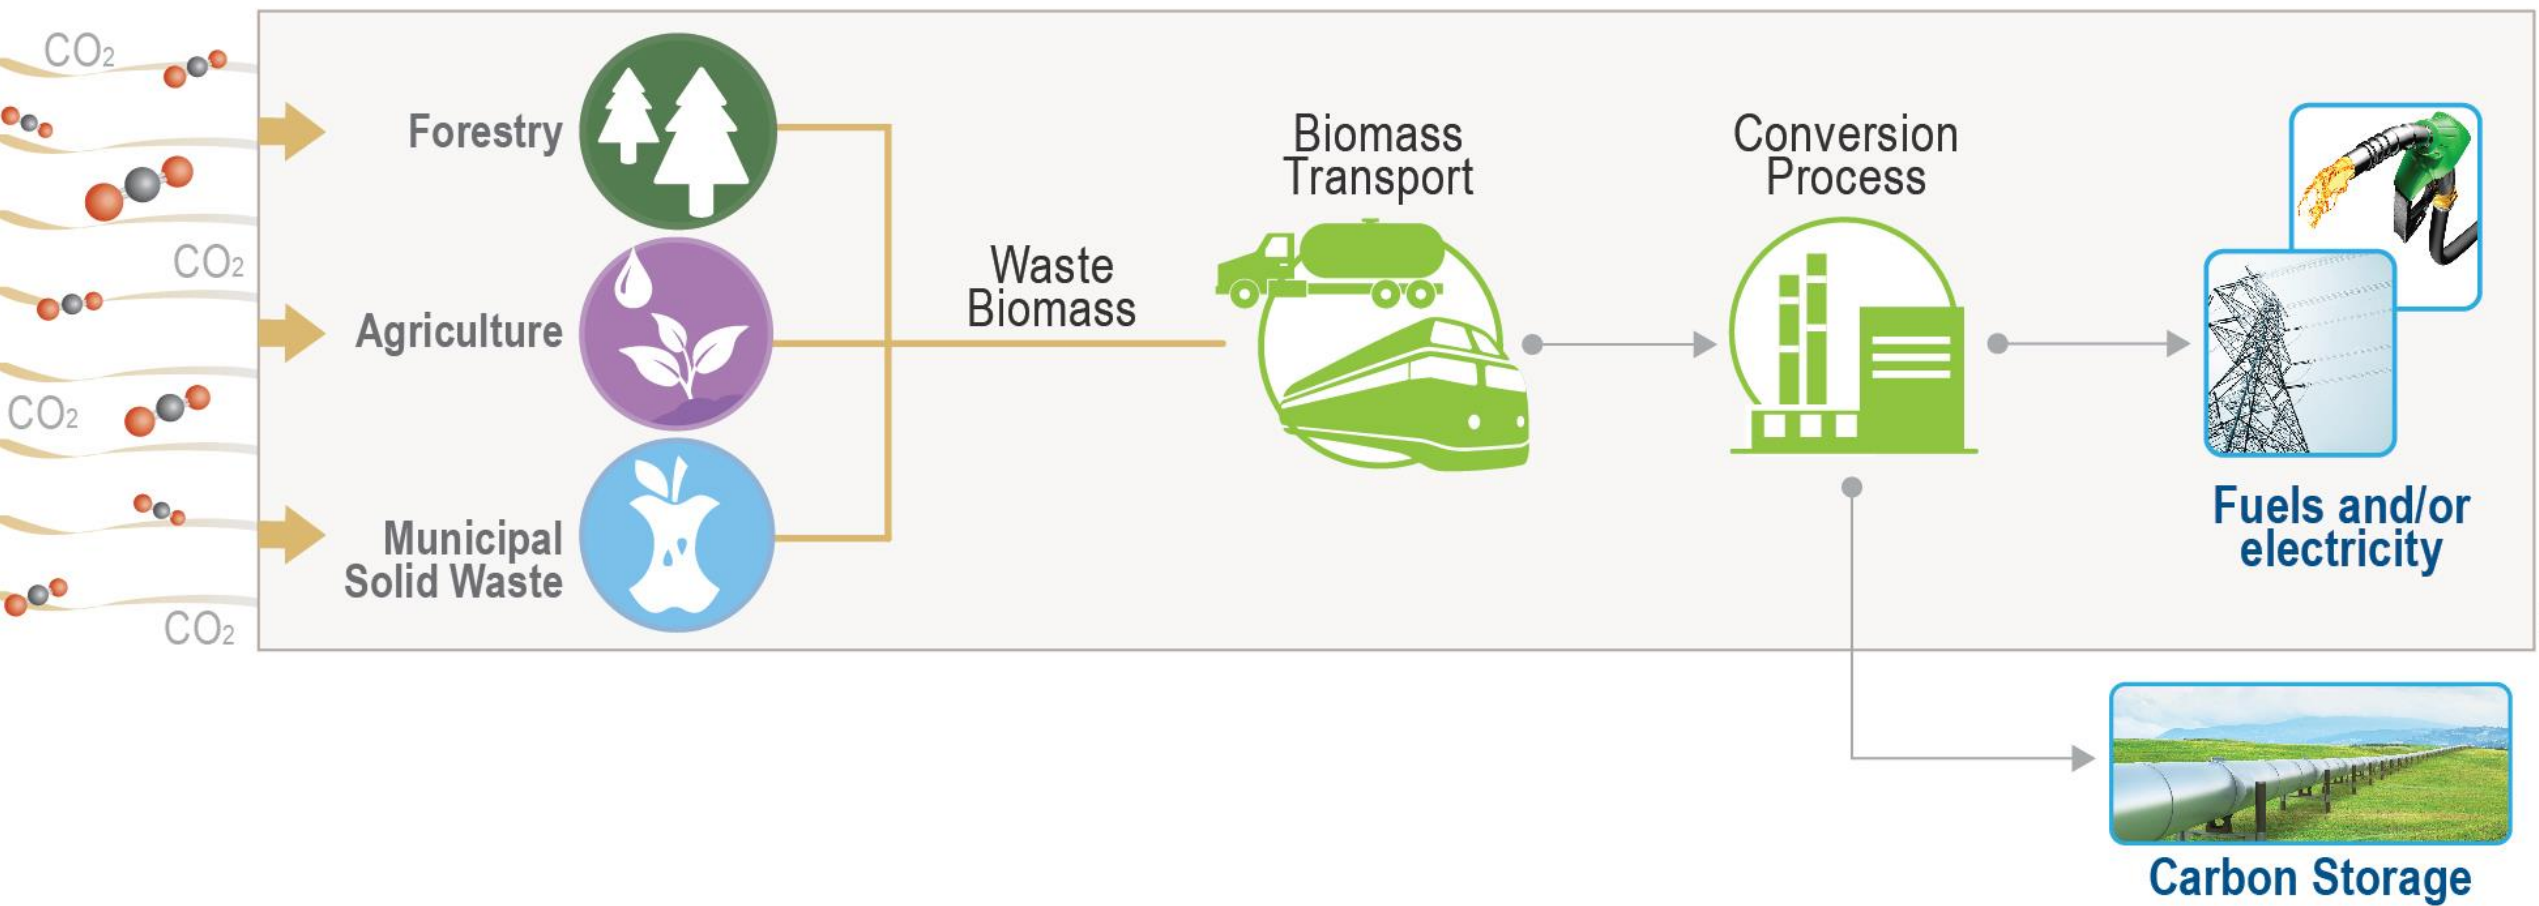

What does it take to obtain climate/environmental benefits from CA's 58 million tons of waste biomass?

- Supply chain
- Gasification
- Manage CO₂ from digesters

BiCRS: Supply Chain and Logistics Pose the Greatest Barriers

Sourcing, siting, and offtake

Gasification of Waste Biomass to Hydrogen:

- highest carbon removal capacity
- lowest cost per ton CO₂
- while reaching state's hydrogen goals

Fulcrum Bioenergy Gasification Facility

Gasification to Hydrogen Barriers to Implementation

County Air Pollution Control District

Sourcing stable long term supply of biomass –
Unique challenges for forest, agriculture, and
municipal waste biomass

High capital cost of facilities to realize
economies of scale means high investment risk

Technology is proven, but feedstock variability
and unique biomass attributes pose technical
risk

Capture of Biogas CO₂ from Dairies, Landfills, and Wastewater Treatment:

- biomass already collected
- conversion technology exists
- generate lower CI renewable natural gas
- avoid flaring

*Flare from
Livermore Water
Reclamation Plant*

Biogas CO₂ Capture: Barriers to Implementation

- small scale distributed CO₂ sources
- lack of economical small scale CO₂ capture technologies

BiCRS Analysis Needs

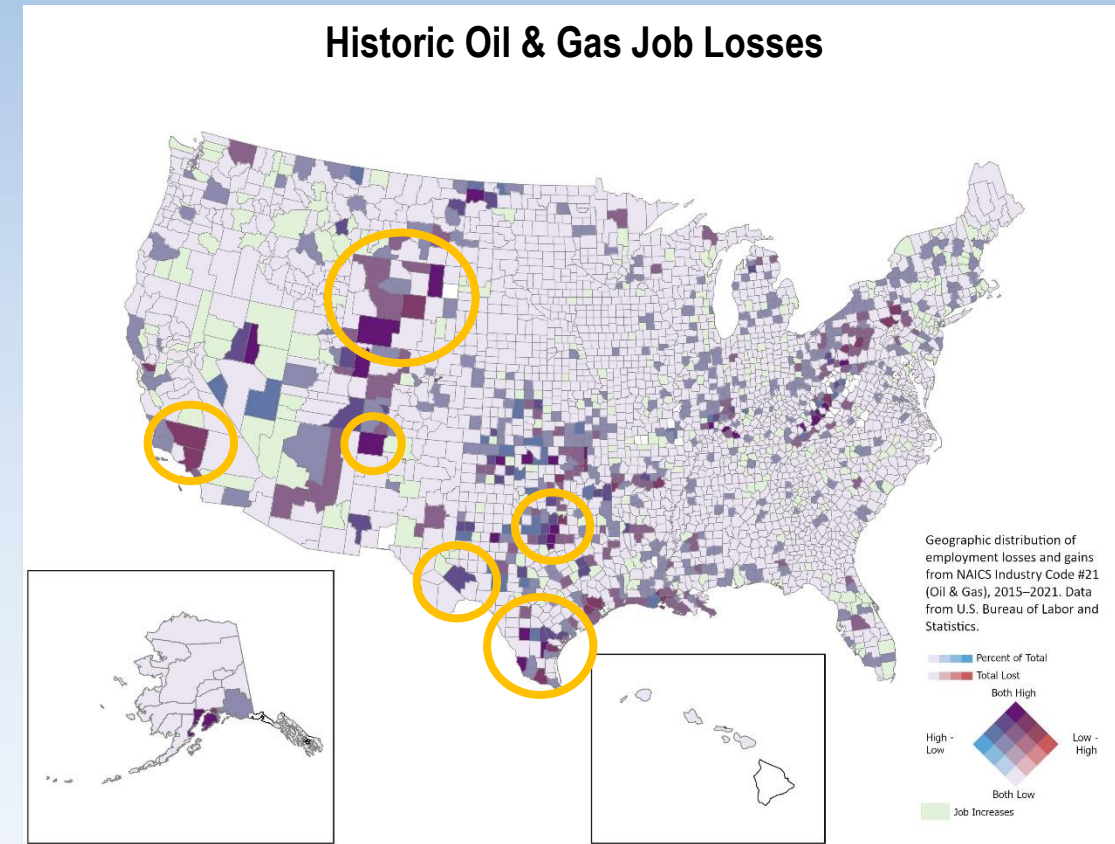

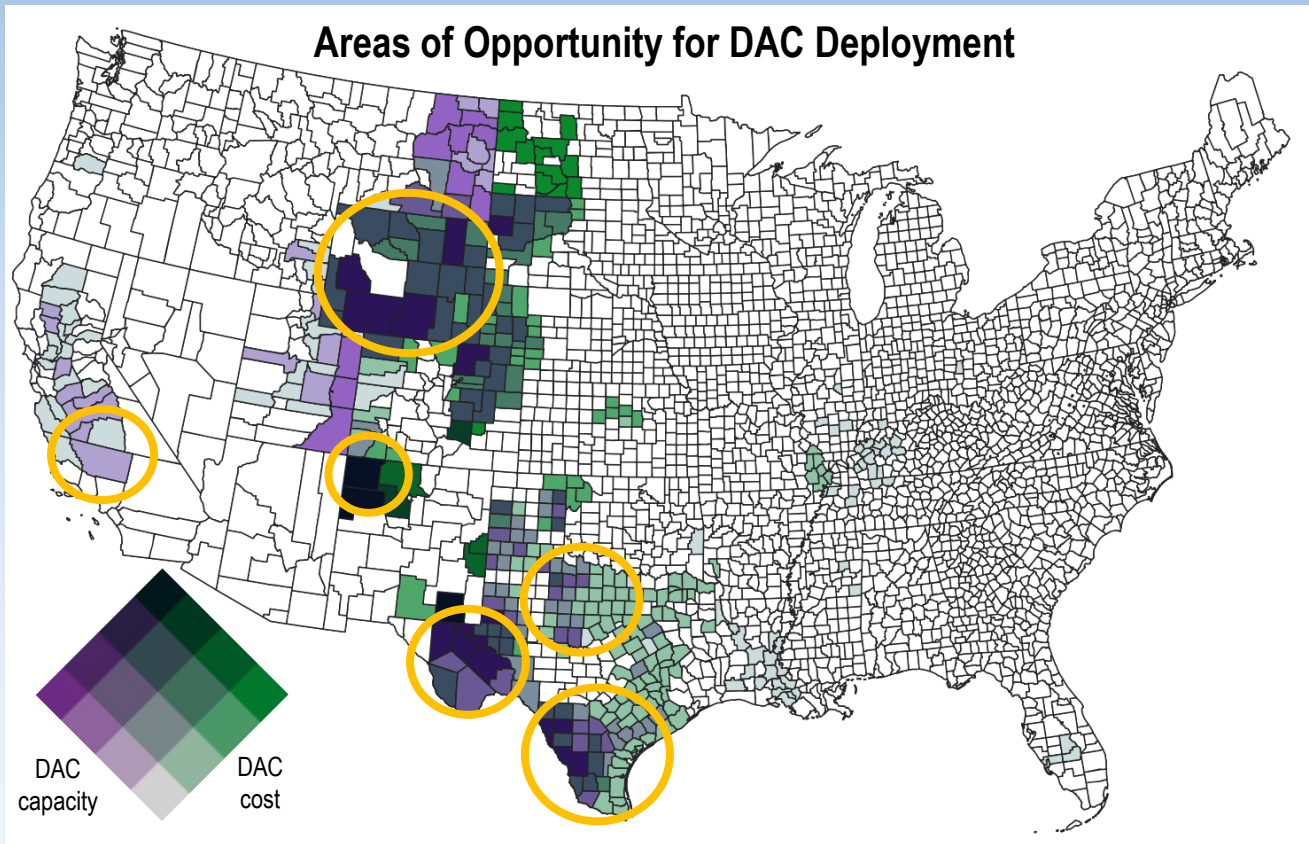

- Deployment rate-what is needed to reach California goals?
- Understanding of highest impact investments to buy down costs
- Needed incentives/risk reduction along the supply chain to catalyze the industry (costs vs. revenue today)

Direct air capture

Chemical filters, solvents, and minerals that absorb CO₂; No reliance on Biomass but higher cost

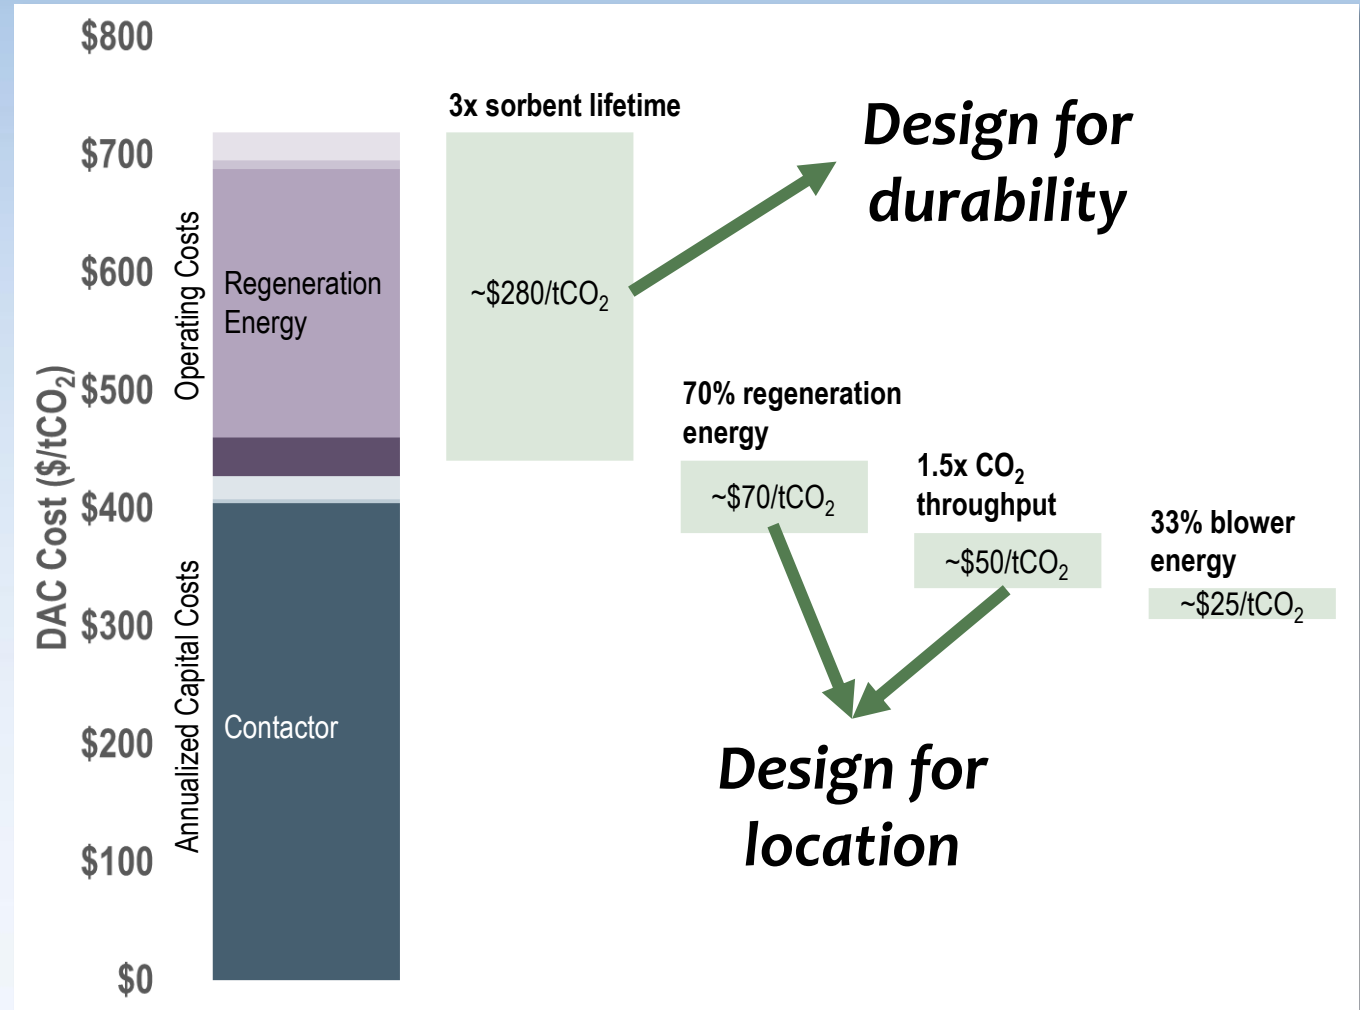

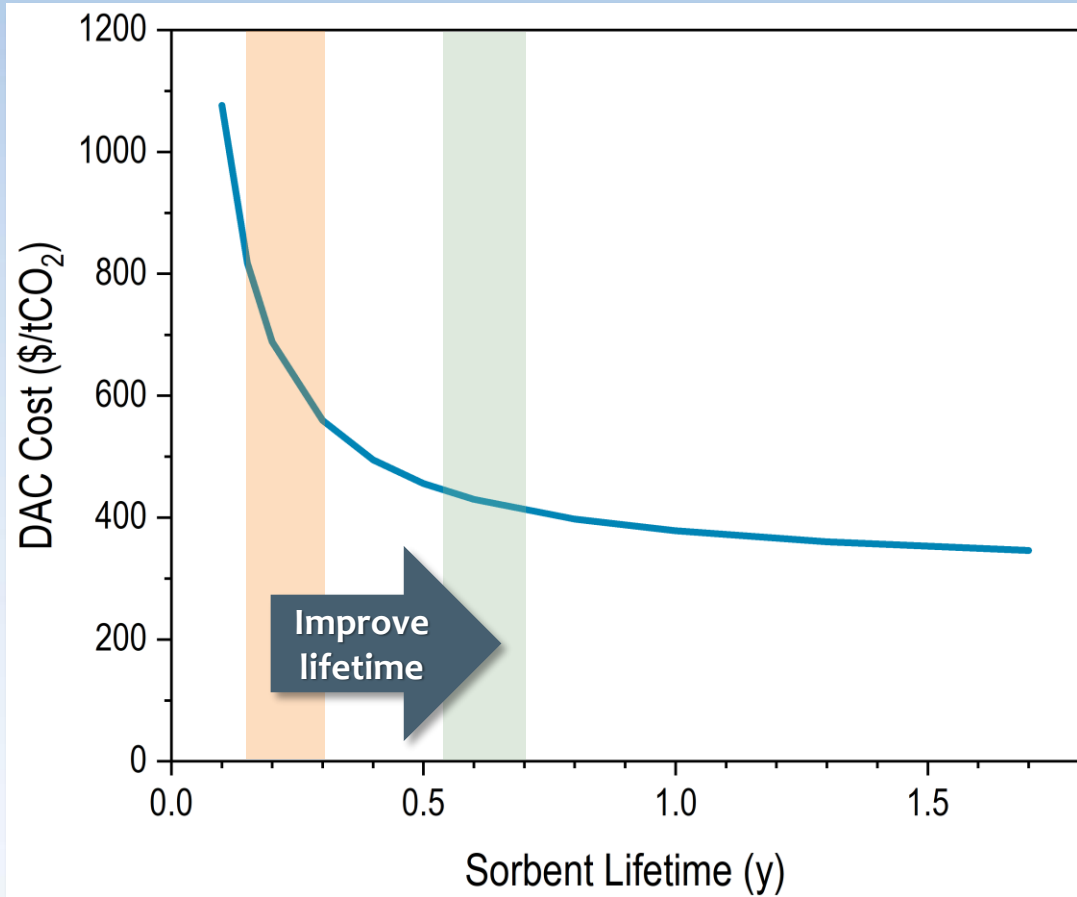

1000 ton per year capture facility, Zurich

California is an area of opportunity for DAC

**How do we design materials tailored for California's central valley (temperature, humidity)?
Can we co-optimize materials, structures, and processes to maximize throughput with minimal energy?**

Results from system- and process-level analysis: improved sorbent durability and design for local and seasonal conditions are needed

In two years carbon removal has boomed

250,000 metric tons of carbon removal over 10 years from STRATOS, [1PointFive](#)'s first DAC plant

Ørsted launches landmark CCS project in Denmark

Microsoft has agreed to purchase 2.76 million tonnes of carbon removal over 11 years from the project, representing one of the world's largest carbon removal offtake agreements to date.

Microsoft has inked one of the largest carbon dioxide removal (CDR) deals to date with Direct Air Capture (DAC) startup Heirloom, which involves 315,000 metric tons of carbon removal estimated to be worth \$200 million.

Boston Consulting Group's *medium scenario* yields a global demand of ~70–230 Mt CO₂ p.a. in 2030–2040, with a market size of ~\$15 billion–\$45 billion. The average voluntary durable CDR portfolio price is assumed at ~\$250/t CO₂ in 2030 and ~\$200/t CO₂ in 2040. North America's share would be roughly 36% of that market.

Commercial CDR is strongly capacity limited today: the market is paying high prices

Total Sales

Total Volume

Total Transactions

Total Expenditure

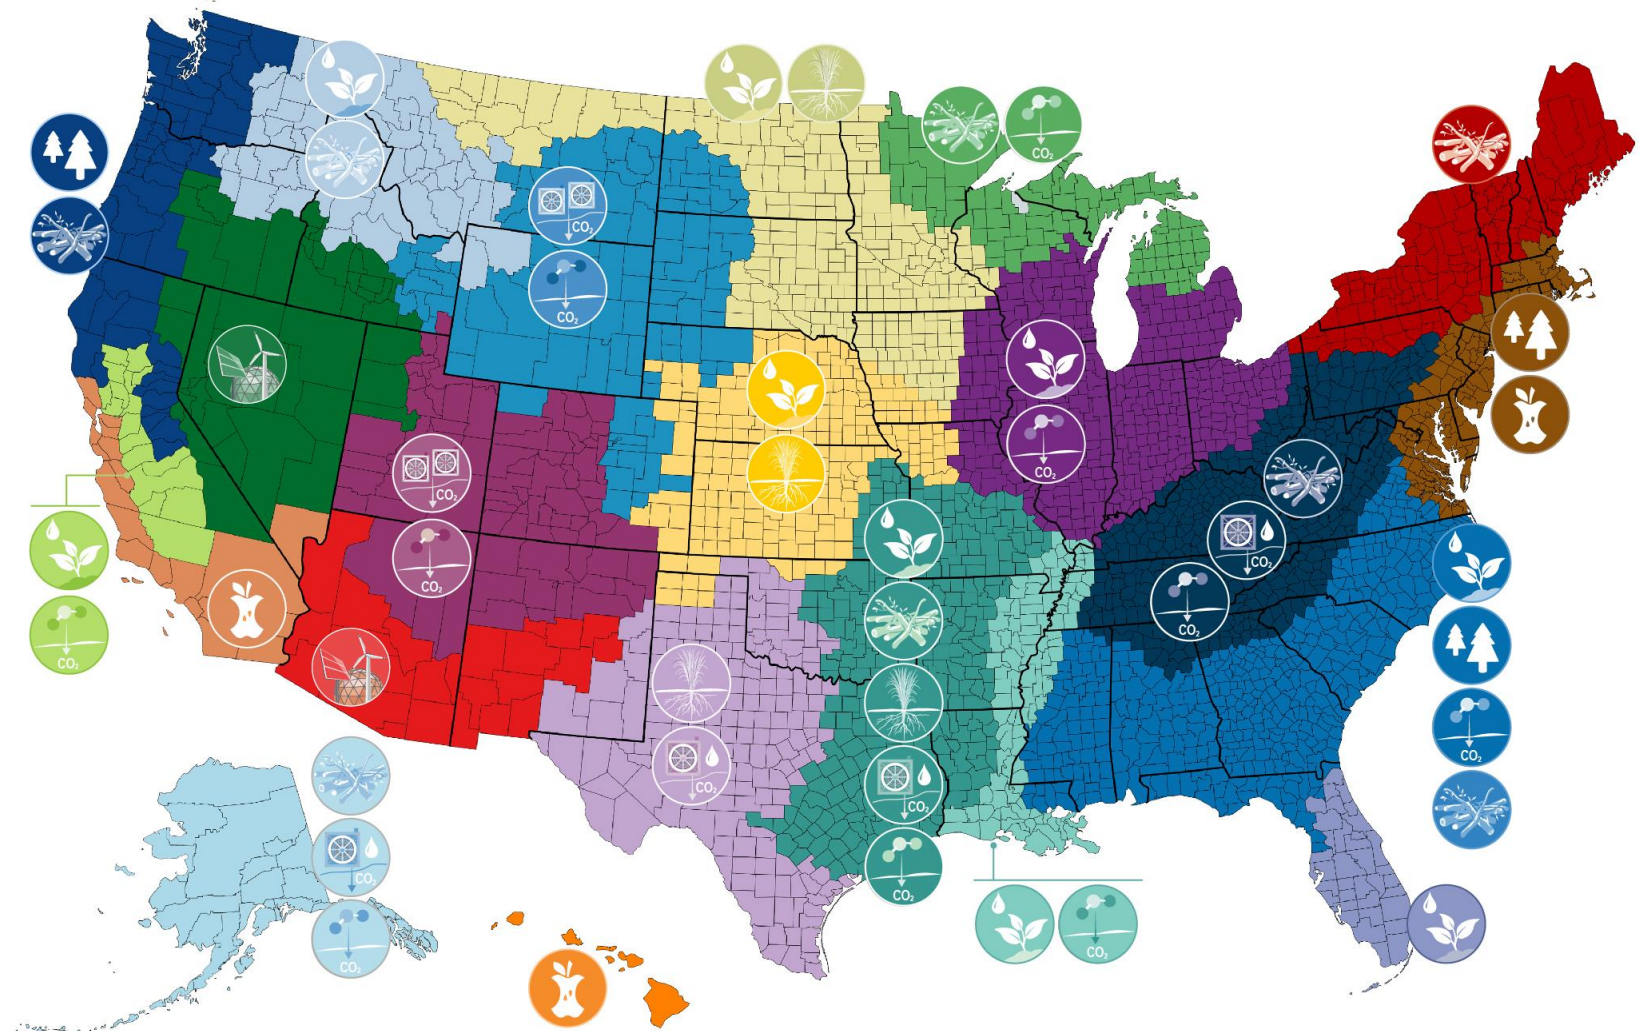

Data from CDR.FYI

Costs vary from \$1200/ton (ocean electrochemical) to \$112 (biomass)

Overall average about \$550/ton

California is Poised to Lead the Nation in Carbon Dioxide Removal

-  Agriculture residues
-  Forest management
-  Forest biomass
-  Cropland soils
-  Municipal solid waste
-  DAC solvent
-  DAC adsorbent
-  Geologic storage
-  Renewable energy

A large white event tent is set up on a grassy field at dusk. The tent is illuminated from within, creating a warm, orange glow. The interior is visible, showing people gathered around tables and a stage area with a band. The sky is a mix of blue and white clouds, and trees are visible in the background. The overall atmosphere is that of an outdoor evening event.

The Getting to Neutral big carbon tent

Our goal is to understand options, connect and inspire players (business, government, community) who want to play a role in carbon removal

EEEJ Considerations

Getting to Neutral Big Ideas:

1. Mother nature can't do it on her own

— *Key outcome for State Legislators*

2. Waste biomass should be used to draw down CO₂ first, rather than emphasize energy

3. H₂ from waste biomass gasification with CO₂ storage is a leading technology for California

Red Rock Biofuels

Robust Solutions Tailored to California

General BiCRS Knowledge and Implementation Gaps

Logistics/Adoption

- Supply chain (Biomass)
- Co-location and multi-stakeholder challenge

Analysis

- Deployment rate-what is needed to reach California goals?
- Understanding of highest impact investments to buy down costs
- Needed incentives/risk reduction along the supply chain to catalyze the industry (costs vs. revenue today)

Technical

- Integration of CO₂ capture with scale of biorefinery
- Biomass feedstock variability
